Network Layer – Part II

Computer Networks, Winter 2015/2016

Network Layer II

- 3.4 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- 3.5 Routing protocols
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol (BGP)

Routing, Forwarding, and Switching

Switching

- Hardware-based relaying of packets
- Relies on switching fabric
- Layer-2 switches, Layer-3 switches

Forwarding

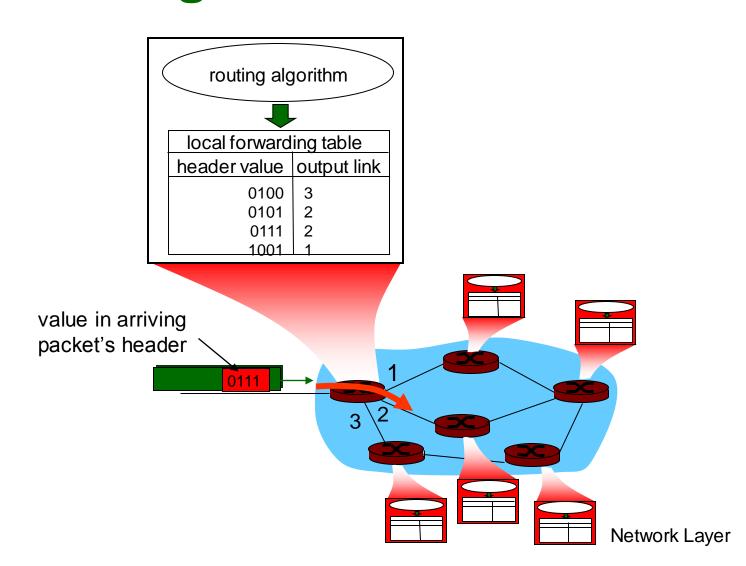

- Relaying of packets from input port to output port(s)
- Based on forwarding table

Routing

Process of configuring the forwarding of a node

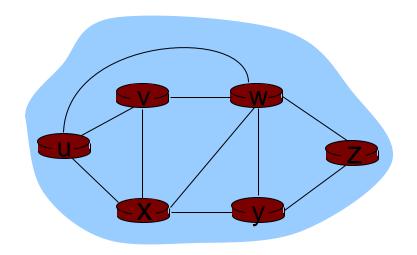

Interplay between routing and forwarding

Graph abstraction

Graph: G = (N,E)

 $N = set of routers = \{ u, v, w, x, y, z \}$

 $E = \text{set of links} = \{ (u,v), (u,x), (v,x), (v,w), (x,w), (x,y), (w,y), (w,z), (y,z) \}$

Remark: Graph abstraction is useful in other network contexts

Example: P2P, where N is set of peers and E is set of TCP connections

Graph abstraction: costs

•
$$c(x,x') = cost of link (x,x')$$

$$- e.g., c(w,z) = 5$$

 cost could always be 1, or inversely related to bandwidth, or inversely related to congestion

Cost of path
$$(x_1, x_2, x_3, ..., x_p) = c(x_1, x_2) + c(x_2, x_3) + ... + c(x_{p-1}, x_p)$$

Question: What's the least-cost path between u and z?

Routing algorithm: algorithm that finds least-cost path

Routing Algorithm classification

Global or decentralized information?

- Global:
 - all routers have complete topology, link cost info
 - o "link state" algorithms
- Decentralized:
 - router knows physicallyconnected neighbors, link costs to neighbors
 - iterative process of computation, exchange of info with neighbors
 - "distance vector" algorithms

Static or dynamic?

- Static:
 - routes change slowly over time
- Dynamic:
 - routes change more quickly
 - periodic update
 - in response to link cost changes

Network Layer II

- 3.4 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- 3.5 Routing protocols
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol (BGP)

A Link-State Routing Algorithm

Dijkstra's algorithm

- net topology, link costs known to all nodes
 - accomplished via "link state broadcast"
 - all nodes have same info
- computes least cost paths from one node ('source") to all other nodes
 - gives forwarding table for that node
- iterative: after k iterations, know least cost path to k dest.'s

Notation

- C(X,y): link cost from node x to y; = ∞ if not direct neighbors
- D(v): current value of cost of path from source to dest. v
- p(v): predecessor node along path from source to v
- N': set of nodes whose least cost path is definitively known

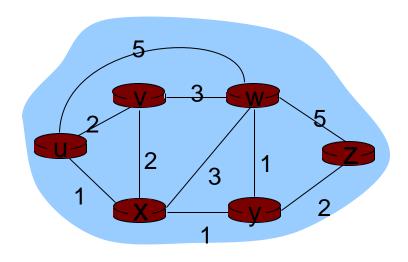

Dijsktra's Algorithm

```
Initialization:
  N' = \{u\}
3 for all nodes v
    if v adjacent to u
       then D(v) = c(u,v)
6
    else D(v) = \infty
   Loop
    find w not in N' such that D(w) is a minimum
   add w to N'
    update D(v) for all v adjacent to w and not in N':
12 D(v) = min(D(v), D(w) + c(w,v))
13 /* new cost to v is either old cost to v or known
    shortest path cost to w plus cost from w to v */
15 until all nodes in N'
```

Dijkstra's algorithm: example

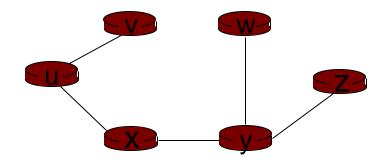

Step	N'	D(v),p(v)	D(w),p(w)	D(x),p(x)	D(y),p(y)	D(z),p(z)
0	u	2,u	5,u	1,u	∞	∞
1	ux←	2,u	4,x		2,x	∞
2	uxy ←	2, u	3,y			4,y
3	uxyv←		3,y			4,y
4	uxyvw ←					4,y
5	uxyvwz ←					_

Dijkstra's algorithm: example (2)

Resulting shortest-path tree from u:

Resulting forwarding table in u:

destination	link
V	(u,v)
X	(u,x)
У	(u,x)
W	(u,x)
Z	(u,x)

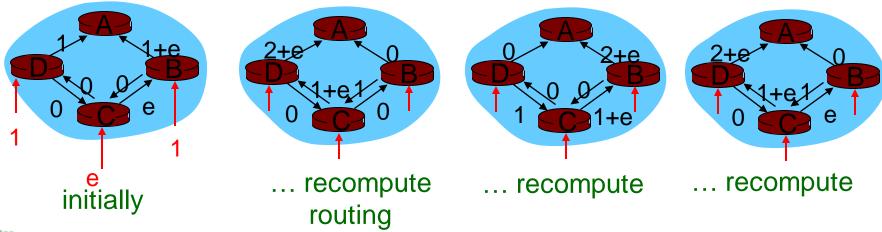

Dijkstra's algorithm, discussion

Algorithm complexity: n nodes

- each iteration: need to check all nodes, w, not in N
- n(n+1)/2 comparisons: O(n²)
- more efficient implementations possible: O(n*log(n))

Oscillations possible:

e.g., link cost = amount of carried traffic

Network Layer II

- 4.4 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- 4.5 Routing protocols
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol (BGP)

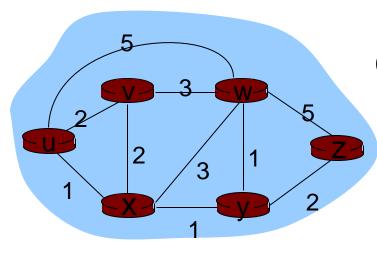

Bellman-Ford algorithm

- Finds shortest paths in weighted, directed graph for given source
- Approach: relax all edges repeatedly until stable (|V| - 1 times)

- Define
 d_x(y) := cost of least-cost path from x to y
- Then $d_x(y) = \min(c(x,v) + d_v(y))$ where min is taken over all neighbors v of x

Bellman-Ford example

Clearly, $d_v(z) = 5$, $d_x(z) = 3$, $d_w(z) = 3$

B-F equation says:

$$d_{u}(z) = \min \{ c(u,v) + d_{v}(z), \\ c(u,x) + d_{x}(z), \\ c(u,w) + d_{w}(z) \}$$

$$= \min \{ 2 + 5, \\ 1 + 3, \\ 5 + 3 \} = 4$$

Node that achieves minimum is next hop in shortest path → forwarding table

Distance Vector Algorithm

- \circ D_x(y) = estimate of least cost from x to y
- Node x knows cost to each neighbor v: c(x,v)
- Node x maintains distance vector D_x = [D_x(y): y ∈ N]
- Node x also maintains its neighbors' distance vectors
 - For each neighbor v, x maintains $\mathbf{D}_{v} = [D_{v}(y): y \in \mathbb{N}]$

Distance vector algorithm – Basic Idea

- From time-to-time, each node sends its own distance vector estimate to neighbors
- Asynchronous
- When a node x receives new DV estimate from neighbor, it updates its own DV using BF equation
 - Dx(y) ← minv{c(x,v) + Dv(y)}
 for each node y ∈ N
- Under minor, natural conditions, the estimate Dx(y) converge to the actual least cost dx(y)

Distance Vector Algorithm (cont'd)

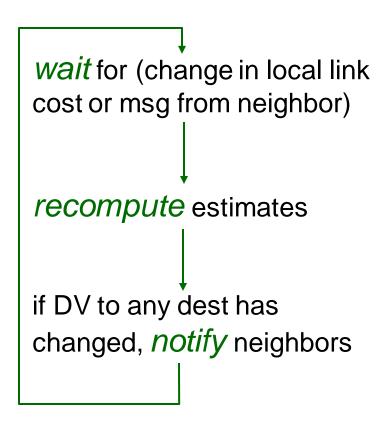

Iterative, asynchronous: each local iteration caused by:

- local link cost change
- DV update message from neighbor

Distributed:

- each node notifies neighbors only when its DV changes
 - neighbors then notify their neighbors if necessary

Each node:

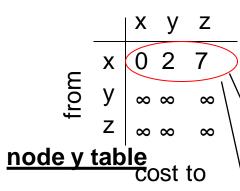

$$D_x(y) = \min\{c(x,y) + D_y(y), c(x,z) + D_z(y)\}$$

= $\min\{2+0, 7+1\} = 2$

 $D_{x}(z) = \min\{c(x,y) +$ $D_y(z)$, $c(x,z) + D_z(z)$

 $= min\{2+1, 7+0\} = 3$

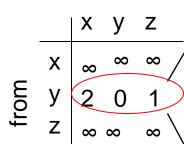

node x table

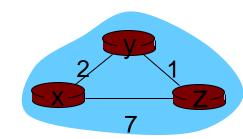

cost to

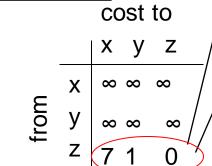

cost to x y

0 X from У

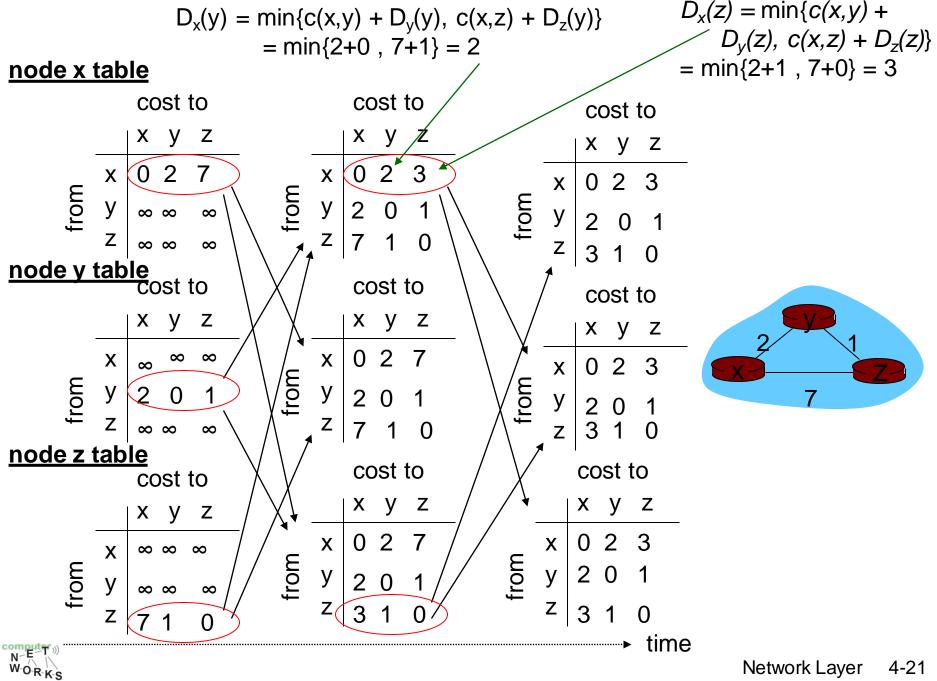

node z table

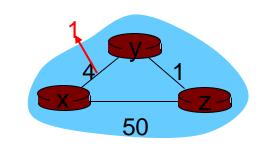

time

Distance Vector: link cost changes

Link cost changes:

- node detects local link cost change
- updates routing info, recalculates distance vector
- if DV changes, notify neighbors

"good news travels fast" At time t_0 , y detects the link-cost change, updates its DV, and informs its neighbors.

At time t_1 , z receives the update from y and updates its table. It computes a new least cost to x and sends its neighbors its DV.

At time t_2 , y receives z's update and updates its distance table. y's least costs do not change and hence y does *not* send any message to z.

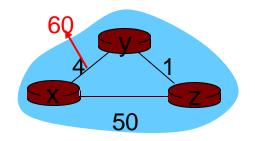

Distance Vector: link cost changes

Link cost changes:

- good news travels fast
- bad news travels slow -"count to infinity" problem!
- 44 iterations before algorithm stabilizes: see textbook

Poisoned reverse:

- If Z routes through Y to get to X :
 - Z tells Y its (Z's) distance to X is infinite (so Y won't route to X via Z)

Comparison of LS and DV algorithms

Message complexity

- LS: with n nodes, E links,
 O(nE) msgs sent
- <u>DV:</u> exchange between neighbors only
 - convergence time varies

Speed of Convergence

- LS: O(n²) algorithm requires
 O(nE) msgs
 - may have oscillations
- <u>DV</u>: convergence time varies
 - may be routing loops
 - count-to-infinity problem

Robustness: what happens if router malfunctions?

LS:

- node can advertise incorrect *link* cost
- each node computes only its own table

DV:

- DV node can advertise incorrect path cost
- each node's table used by others
 - error propagate through network

Network Layer II

- 3.4 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- 3.5 Routing protocols
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol (BGP)

Hierarchical Routing

- Our routing study thus far idealization
 - all routers identical
 - network "flat"
 - ... not true in practice
- Scale: with 200 million destinations:
 - o can't store all dest's in routing tables
 - routing table exchange would swamp links
- Administrative autonomy
 - internet = network of networks
 - each network admin may want to control routing in its own network

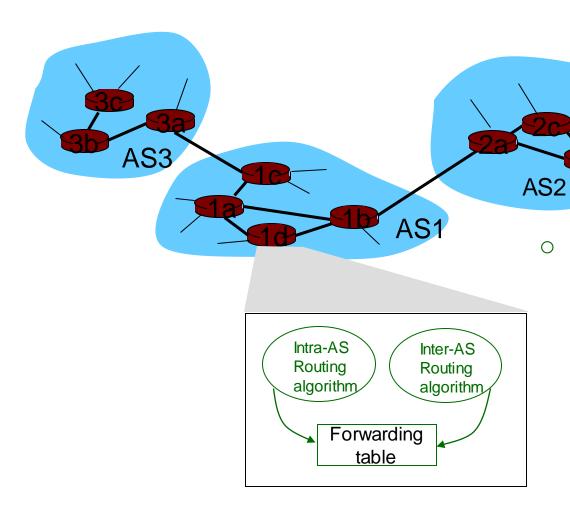

4-26

Hierarchical Routing

- Aggregate routers into regions
 - Autonomous Systems (AS)
- Routers in same AS run same routing protocol
 - "intra-AS" routing protocol
 - routers in different AS can run different intra-AS routing protocol
- Gateway router
 - Direct link to router in another AS

Interconnected ASes

 forwarding table configured by both intra- and inter-AS routing algorithm

- intra-AS sets entries for internal dests
- inter-AS & intra-As sets entries for external dests

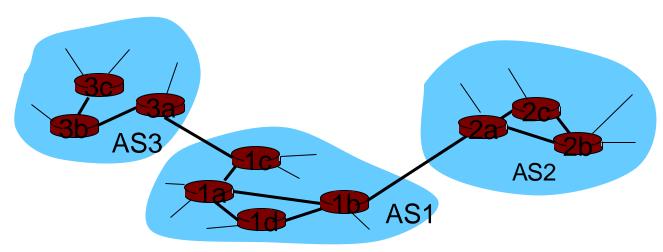

Inter-AS tasks

- suppose router in AS1 receives datagram destined outside of AS1:
 - router should forward packet to gateway router, but which one?

AS1 must:

- learn which dests are reachable through AS2, which through AS3
- propagate this reachability info to all routers in AS1

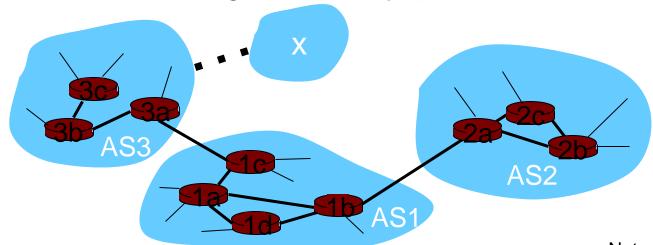

Job of inter-AS routing!

Example: Setting forwarding table in router 1d

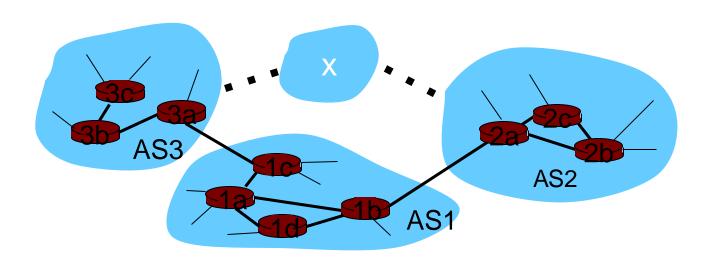

- suppose AS1 learns (via inter-AS protocol) that subnet x reachable via AS3 (gateway 1c) but not via AS2.
- inter-AS protocol propagates reachability info to all internal routers.
- router 1d determines from intra-AS routing info that its interface / is on the least cost path to 1c.
 - installs forwarding table entry (x,l)

Example: Choosing among multiple ASes

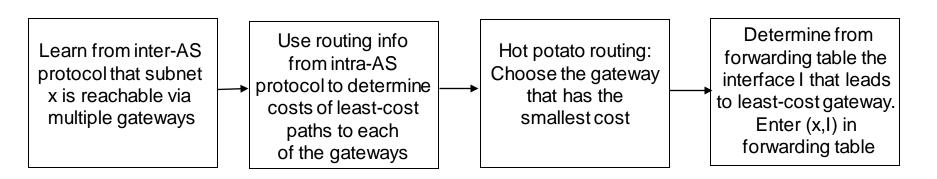

- now suppose AS1 learns from inter-AS protocol that subnet x is reachable from AS3 and from AS2.
- to configure forwarding table, router 1d must determine towards which gateway it should forward packets for dest x.
 - this is also job of inter-AS routing protocol!

Example: Choosing among multiple ASes

- now suppose AS1 learns from inter-AS protocol that subnet x is reachable from AS3 and from AS2.
- to configure forwarding table, router 1d must determine towards which gateway it should forward packets for dest x.
 - o this is also job of inter-AS routing protocol!
- hot potato routing: send packet towards closest of two routers.

Network Layer II

- 3.4 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- 3.5 Routing protocols
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol (BGP)

Routing Protocols

- Intra-AS routing aka Interior Gateway Protocols (IGP)
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Interior Gateway Routing Protocol (IGRP) (Cisco proprietary)
- Inter-AS routing
 - Border Gateway Protocol (BGP)
 - Exterior Gateway Protocol (EGP)

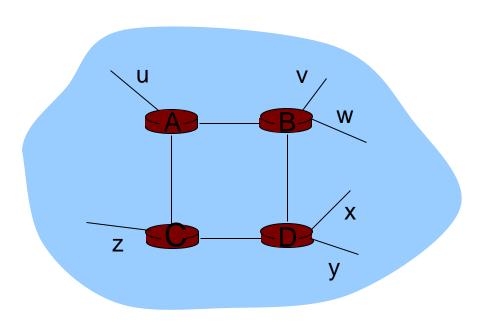

Network Layer II

- 3.4 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- 3.5 Routing protocols
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol (BGP)

Routing Information Protocol (RIP)

- distance vector algorithm
- o included in BSD-UNIX Distribution in 1982
- distance metric: # of hops (max = 15 hops)

From router A to subnets:

<u>destination</u>	<u>hops</u>
u	1
V	2
W	2
X	3
У	3
Z	2

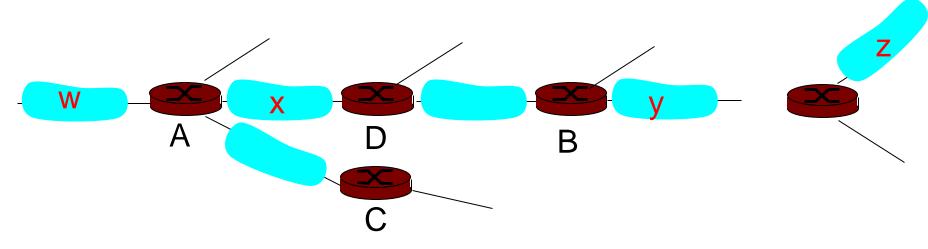

RIP advertisements

- distance vectors
 - exchanged among neighbors every 30 sec via
 Response Message (also called advertisement)
- each advertisement: list of up to 25 destination subnets within AS

RIP: Example

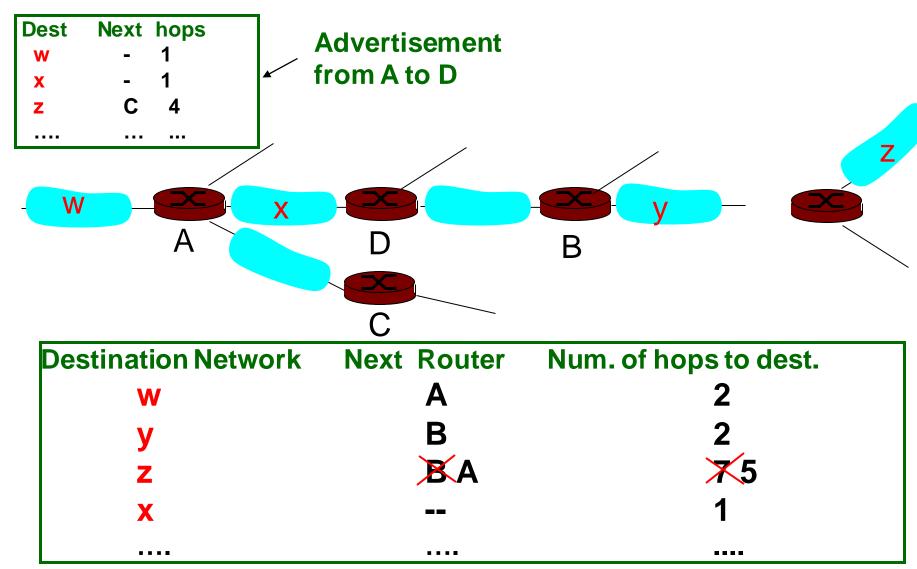

Destination Network	Next Router	Num. of hops to dest.
W	Α	2
y	В	2
Z	В	7
X		1
	••••	

Routing/Forwarding table in D

RIP: Example

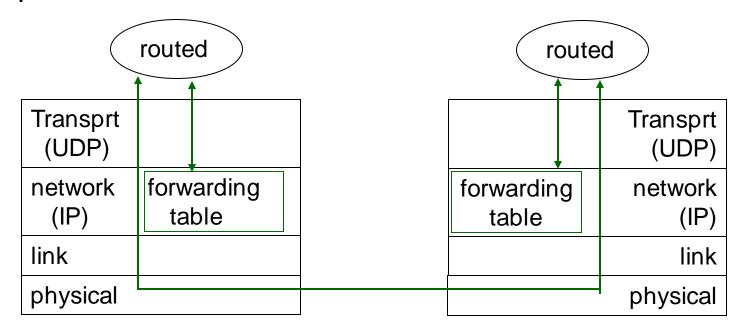

RIP: Link Failure and Recovery

- If no advertisement heard after 180 sec:
 neighbor/link declared dead
 - routes via neighbor invalidated
 - new advertisements sent to neighbors
 - neighbors in turn send out new advertisements (if tables changed)
 - link failure info quickly (?) propagates to entire net
 - poison reverse used to prevent ping-pong loops (infinite distance = 16 hops)

RIP Table processing

- RIP routing tables managed by application-level process called route-d (daemon)
- advertisements sent in UDP packets, periodically repeated

Network Layer II

- 3.4 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- 3.5 Routing protocols
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol (BGP)

Open Shortest Path First (OSPF)

- o "open": publicly available
- uses Link State algorithm
 - LS packet dissemination
 - topology map at each node
 - route computation using Dijkstra's algorithm
- OSPF advertisement carries one entry per neighbor router
- advertisements disseminated to entire AS (via flooding)
 - carried in OSPF messages directly over IP (rather than TCP or UDP

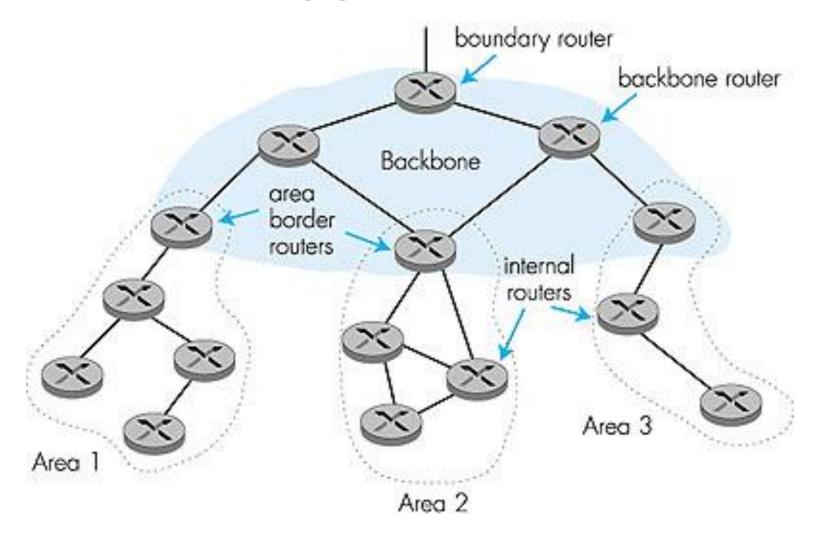

OSPF "advanced" features (not in RIP)

- Security: all OSPF messages authenticated (to prevent malicious intrusion)
- multiple same-cost paths allowed
- For each link, multiple cost metrics for different TOS
- Integrated uni- and multicast support:
 - Multicast OSPF (MOSPF) uses same topology data base as OSPF
- Hierarchical OSPF in large domains.

Hierarchical OSPF

Hierarchical OSPF

- two-level hierarchy: local area, backbone.
 - Link-state advertisements only in area
 - each node has detailed area topology; only know direction (shortest path) to nets in other areas.
- area border routers: "summarize" distances to nets in own area, advertise to other Area Border routers.
- backbone routers: run OSPF routing limited to backbone.
- boundary routers: connect to other AS's.

Network Layer II

- 3.4 Routing algorithms
 - Link state
 - Distance Vector
 - Hierarchical routing
- 3.5 Routing protocols
 - Routing Information Protocol (RIP)
 - Open Shortest Path First (OSPF)
 - Border Gateway Protocol (BGP)

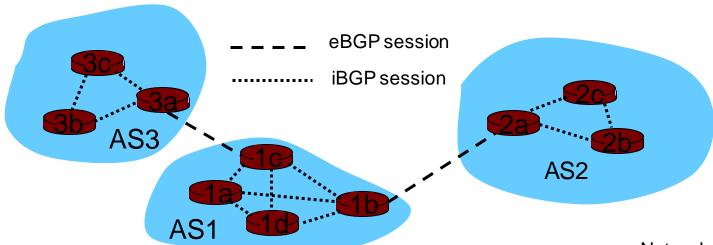

Inter-AS routing: BGP

- BGP (Border Gateway Protocol): the de facto standard
- BGP provides each AS means to:
 - Obtain subnet reachability information from neighboring ASs.
 - Propagate reachability information to all ASinternal routers.
 - Determine "good" routes to subnets based on reachability information and policy.
- allows subnet to advertise its existence to rest of Internet: "I am here"

BGP basics

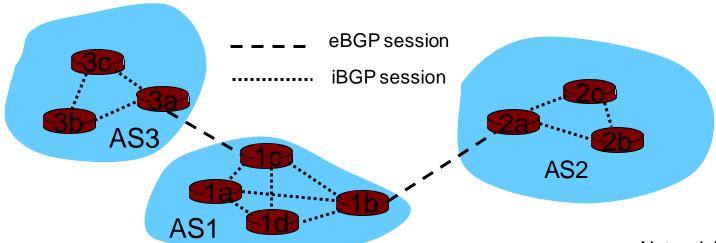

- pairs of routers (BGP peers) exchange routing info over BGP sessions (semi-permanent TCP connections):
 - BGP sessions need not correspond to physical links.
- o when AS2 advertises a prefix to AS1:
 - AS2 promises it will forward datagrams towards that prefix.
 - AS2 can aggregate prefixes in its advertisement

Distributing reachability info

- using eBGP session between 3a and 1c, AS3 sends prefix reachability info to AS1.
 - 1c can then use iBGP do distribute new prefix info to all routers in AS1
 - 1b can then re-advertise new reachability info to AS2 over 1b-to-2a eBGP session
- when router learns of new prefix, it creates entry for prefix in its forwarding table.

Path attributes & BGP routes

- advertised prefix includes BGP attributes.
 - o prefix + attributes = "route"
- two important attributes:
 - AS-PATH: contains ASs through which prefix advertisement has passed: e.g, AS 67, AS 17
 - NEXT-HOP: indicates specific internal-AS router to next-hop AS. (may be multiple links from current AS to next-hop-AS)
- when gateway router receives route advertisement, uses import policy to accept/decline.

BGP route selection

- Router may learn about more than 1 route to same prefix:
 - Router must select route
- o Elimination rules:
 - Local preference value attribute: policy decision
 - Shortest AS-PATH
 - Closest NEXT-HOP router: hot potato routing
 - Additional criteria

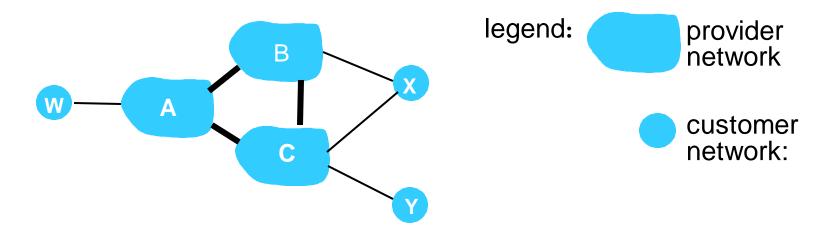

BGP messages

- BGP messages exchanged using TCP
- BGP messages:
 - OPEN: opens TCP connection to peer and authenticates sender
 - UPDATE: advertises new path (or withdraws old)
 - KEEPALIVE keeps connection alive in absence of UPDATES; also ACKs OPEN request
 - NOTIFICATION: reports errors in previous msg;
 also used to close connection

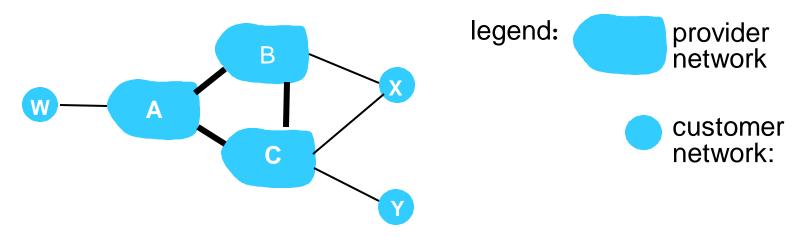

BGP routing policy

- A,B,C are provider networks
- X,W,Y are customer networks
- X is dual-homed: attached to two networks
 - X does not want to route from B via X to C
 - .. so X will not advertise to B a route to C

BGP routing policy (2)

- A advertises path AW to B
- B advertises path BAW to X
- Should B advertise path BAW to C?
 - No way! B gets no "revenue" for routing CBAW since neither W nor C are B's customers
 - B wants to force C to route to w via A
 - B wants to route only to/from its customers!

Why different Intra- and Inter-AS routing?

Policy

- Inter-AS: admin wants control over how its traffic routed, who routes through its net.
- Intra-AS: single admin, so no policy decisions needed

Scale

 hierarchical routing saves table size, reduced update traffic

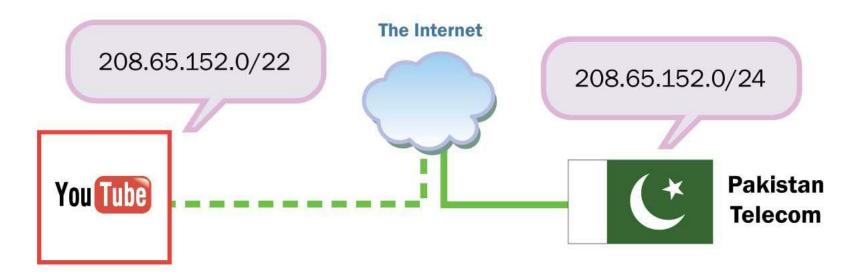

Performance

- Intra-AS: can focus on performance
- Inter-AS: policy may dominate over performance

Current Research

- Software-defined networking
- BGP: mainly security issues

Thank you

Any questions?
