- Evolutionary random search Overview History
 - Limitations
 - Design aspects

Local random search heuristics

- Local random search
 - Intuitive way to climb a mountain (by a sightless climber)

Local random search

 $\forall x \text{ in search space } S$, define non-empty neighbourhood $N(x) \subseteq S$ Iteratively draw one random sample $x' \in N(x)$. Fitness improved $(F(x) > F(x')) \Rightarrow$ new best search point. <u>Otherwise</u> \Rightarrow discarded.

Local random search heuristics

N(x) = x or N(x) = S valid, but original idea is that N(x) is small set of search points.

Points $x' \in N(x)$ expected nearer to x than points $x'' \notin N(x)$ Typically, $x \in N(x)$

Local random search heuristics

Complexity reduction by restriction of the search space size

Example:
$$S = \{0,1\}^n$$
 and $N_d(x)$ are all
points y with Hamming distance smaller
than $d (H(x,y) \le d)$
• For constant d we obtain:
 $|N_d(x)| = \Theta(n^d) \ll |S| = 2^n$
 $|N_d(x)| = \begin{pmatrix} n \\ d \end{pmatrix} + \begin{pmatrix} n \\ d-1 \end{pmatrix} + \dots + \begin{pmatrix} n \\ 1 \end{pmatrix} + \begin{pmatrix} n \\ 0 \end{pmatrix}$

Machine Learning and Pervasive Computing

Evolutionary algorithms

Initialisation

- Initialise μ individuals from the search space S
- Typically uniformly at random
- Typical search spaces: $S = \mathbb{R}^n$ or $S = \mathbb{B}^n$
- Achieve sufficient coverage:
 - Distance measure d
 - distance $\geq d$
- Improve optimisation time and quality of solution:
 - fast heuristics for individual population

イロト イポト イヨト イヨト

Evolutionary algorithms

Fitness weighting of the population

- Individuals of population weighted for their fitness value.
- Fitness function $f: S \to \mathbb{R}$
- Monotonous function

イロン 不同 とくほう イヨン

Machine Learning and Pervasive Computing

Selection for reproduction

- Dependent on fitness values reached by individuals
- individuals chosen to produce offspring population
- Intuition:
 - Individuals with good fitness value: Higher probability to produce high-rated individuals for offspring population

Machine Learning and Pervasive Computing

Variation

- Offspring population created by mutation and/or crossover.
- Mutation is typically local search operator
- Crossover allows to find search points in currently not populated regions
- Adaptive implementations possible

Machine Learning and Pervasive Computing

Mutation

- Produces individuals that differ only slightly from the parent-individuals.
- One parent individual produces one offspring individual
- Mutation operators differ between search spaces.

・ロ・・@・・E・・E・ E のへで

Evolutionary algorithms

Crossover

Crossover is a variation technique that produces one or more offspring individuals from two or more parent individuals

・ 日本・ (四本・ (日本・ (日本・ (日本))

- All newly generated offspring individuals are weighted by a fitness function *f*.
- Structure of *f* impacts performance of random search approach
 - Weak multimodal vs. strong multimodal

Machine Learning and Pervasive Computing

Selection for substitution

- Population size increased due to variation
- Reduce population size to μ
- Typically: Individuals with higher fitness values more probable

Machine Learning and Pervasive Computing

Machine Learning and Pervasive Computing
Evolutionary algorithms History – Genetic algorithms

• Proposed by John Holland ¹

- Binary discrete search spaces: $\{0,1\}^n$
- Fitnessproportional selection
 - For *m* individuals x_1, \ldots, x_m the probability to choose x_i is $\frac{f(x_i)}{f(x_1)+\cdots+f(x_m)}$.
- Main evolution operator is crossover
 - Originally One-point crossover
- The main goal was not optimisation but the adaptation of an environment

¹ J. Holland, Adaptation in Natural and Artificial Systems, University of Michigan Press, 1975. 🕢 🚊 🚽 🖓 🔍 🕐

イロト 不得 とくほと くほとう ほ

Machine Learning and Pervasive Computing

Evolutionary algorithms History – Genetic algorithms

• The hope associated with genetic algorithms was that they are able to solve some functions especially well

Separable function

A function is called separable, if the input variables can be divided into disjoint sets X_1, \ldots, X_k with $f(x) = f_1(X_1) + \cdots + f_k(X_k)$

• Since genetic algorithms utilise crossover, it was expected that they are therefore well suited to quickly find the optimum on separable functions

History – Genetic algorithms

Royal road functions

k blocks of variables of length l are formed. On each block X_l the identical function f_l is implemented with

$$f_l(X_l) = \begin{cases} 1 & \text{All variables in } X_l \text{ equal } 1 \\ 0 & else. \end{cases}$$

- $\bullet\,$ It was shown that genetic algorithms do NOT perform well on these functions.^2
- The reason is that it is highly unlikely to perform crossover exactly at the border of the variable blocks.
- It is better to optimise the single blocks on their own separately by mutation.

²T. Jansen and I. Wegener, Real royal road functions – where crossover provably is essential, Discrete applied

Evolutionary algorithms History – Evolution strategies

- \bullet Proposed by Bienert, Rechenberg and Schwefel^{3 4}
- At first only steady search spaces as \mathbb{R}^n
- No Crossover
- Only mutation
 - First mutation operator: Each component x_i is replaced by $x_i + Z_i$ (Z_i normally distributed, σ^2 Variance)

⁴H.P. Schwefel, *Evolution and optimum seeking*, 1993

Machine Learning and Pervasive Computing

Evolutionary algorithms History – Evolution strategies

1 /F I

1/5 rule

After 10*n* iterations, the variance is adopted every *n* iterations. When the number of accepted mutations in the last 10*n* steps is greater than 1/5, σ is divided by 0.85 and else multiplied by 0.85.

• This heuristic is based on an analysis of the fitness function x_1^2, \ldots, x_n^2 – the sphere model.

Machine Learning and Pervasive Computing

イロト 不得 トイヨト イヨト 二日

Evolutionary algorithms History – Evolutionary programming

- The approach was proposed by Lawrence J. Fogel⁵⁶
- Various similarities to evolution strategies
- Search Space: Space of deterministic finite automata.

⁵L.J. Fogel, *Autonomous automata*, Industrial Research, Vol. 4, 1962.

Evolutionary algorithms History – Genetic programming

- Proposed by John Koza⁷
- Search space: Syntactically correct programs
- Crossover more important than mutation

¹ John Koza Genetic Programming: On the Programming of Computers by Means of Natural Selection, MIT Press, 1992

- Since evolutionary approaches are typically slow to initially find a search point with a reasonable fitness value,
- Approaches are combined with fast heuristics that initially search for a good starting point.
- Afterwards the evolutionary approach is applied

◆□ → ◆□ → ◆ ■ → ◆ ■ → ● ■ 一 の Q ○ Machine Learning and Pervasive Computing

It has been argued that

- Problem specific algorithms better than evolutionary on small subset of problems
- Evolutionary algorithms better on average over all problems

Can one algorithm be better on average than another algorithm on 'all' problems?

Can an algorithm be suited for 'all' problems?

- Distinct coding of the search space
- Various fitness functions

What does 'all problems' mean?

- All possible representations and sizes of search space
- All possible fitness functions
- Every single point is the optimum point in several of these problems

Can one algorithm be better on average than another algorithm on 'all' problems?

Machine Learning and Pervasive Computing

イロト 不得 トイヨト イヨト 二日

Wolpert and Macready formalised this assertion:⁸

- **F** Set of all functions $f: S \to W$
- S and W finite (every computation on physical computers only has finite resources)
- Fitness function evaluated only once per search point
- A(f) number of points evaluated until optimum is found

⁸D.H. Wolpert and W.G. Macready, *No Free Lunch Theorems for Optimisation*, IEEE Transactions on Evolutionary Computation 1, 67, 1997.

イロト 不得 トイヨト イヨト 二日

Machine Learning and Pervasive Computing

Limitations of evolutionary approaches

No free lunch theorem

Assume that the average performance of an algorithm in the No Free Lunch Scenario for S and W is given by $A_{S,W}$, the average over all $A(f), f \in F$. Given two algorithms A and A', we obtain $A_{S,W} = A'_{S,W}$

• This means that two arbitrary algorithms perform equally well on average on all problems

Proof of the No Free Lunch Theorem

W.l.o.g.: $W = \{1, ..., N\}$

We consider sets $F_{s,i,N}$ of all functions f on a search space of non-visited search points of size s with at least one x with f(x) > iObserve that for every function f and every permutation π also f_{π} belongs to $F_{s,i,N}$

Proof of the No Free Lunch Theorem

Proof by induction over s := |S|. Induction start: s = 1

Every algorithm has to choose the single optimum search point with its first request.

・ロト・雪・・ヨ・・ヨー めんの

Proof of the No Free Lunch Theorem

Induction: $s - 1 \rightarrow s$ Define $a: S \rightarrow \mathbb{N}$ so that $\forall x \in S$ the share of functions with f(x) = j is exactly a(j).

This is independent of x, since all permutations f_{π} of a function f also belong to $F_{s,i,N}$

a(j) is therefore the probability to choose a search point with fitness value j (Independent of the concrete algorithm A)

Machine Learning and Pervasive Computing

イロト 不得 とくほと くほとう ほ

Proof of the No Free Lunch Theorem

Induction: $s - 1 \rightarrow s$

With probability a(j) an algorithm A finds a search point with fitness value j.

Count of functions f(x) = j is equal to the number of functions $f_{\pi}(y) = j$, since all permutations of f are also in $F_{s,i,N}$.

The probability to achieve a fitness value j > i is therefore independent of the algorithm.

◆□ → < 部 → < ■ → < ■ → ■ の Q ペ Machine Learning and Pervasive Computing

Proof of the No Free Lunch Theorem

Induction: $s - 1 \rightarrow s$

With probability a(j) an algorithm A finds a search point with fitness value j.

If $j \leq i$, x is not optimal in scenario $F_{s,i,N}$ and the new scenario is $F_{s-1,i,N}$

◆□ → < 団 → < 置 → < 置 → < 置 → の Q ペ Machine Learning and Pervasive Computing

Machine Learning and Pervasive Computing

3

Limitations of evolutionary approaches

Proof of the No Free Lunch Theorem

Summary – in other words:

For any two algorithms we can state a suitable permutation of the Problem-function for one problem (i.e. state another problem), so that both algorithms in each iteration request identical search points.

• Especially, since every search point could be optimal, there are always algorithms that request the optimal search point right from the start.

 NFL is possible, since ALL algorithms and ALL problems are considered

Is there an NFL valid in smaller, more realistic scenarios?

In 9 a similar theorem was proved for more realistic problem scenarios.

Design aspects of evolutionary algorithms Selection principles

Uniform selection

Individuals chosen uniformly at random

Deterministic selection

Deterministically choose the highest rated individuals for the selection

Threshold selection

Candidates for offspring population drawn uniformly at random from the t highest rated individuals

Machine Learning and Pervasive Computing

イロト 不得 とくほと くほとう ほ

Design aspects of evolutionary algorithms

Selection principles

Fitnessproportional selection

• For population x_i, \ldots, x_n individual x_i chosen with

$$p(x_i) = \frac{f(x_i)}{f(x_1) + \cdots + f(x_n)}$$

• Draw random variable u from [0, 1] and consider x_i if

$$p(x_1) + \cdots + p(x_{i-1}) < u \leq p(x_1) + \cdots + p(x_i)$$

• Frequently applied for evolutionary approaches

Machine Learning and Pervasive Computing

Design aspects of evolutionary algorithms Selection principles

- Problems with Fitnessproportional selection
 - Linear modification of the fitness function $(f \rightarrow f + c)$ results in different behaviour
 - When fitness values sufficiently separated, selection is nearly deterministic
 - When deviation in fitness values is small relative to absolute values, similar to uniform selection

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Design aspects of evolutionary algorithms

Variation operators – Mutation

- Mutation creates one offspring individual from one individual
- Operators are designed for specific search spaces
- Shall apply only few modifications of individuals on average
- Distant individuals have smaller probability

Variation operators – Mutation

Mutation operators for individuals from \mathbb{B}^n (similar operators for other search spaces):

Standard bit mutation

- Offspring individual created bit-wise from parent individual
- Every bit 'flipped' with probability p_m
- Common choice: $p_m = \frac{1}{n}$

1 bit mutation

- Offspring individual identical in all but one bit.
- This bit chosen uniformly at random from all *n* bits

Machine Learning and Pervasive Computing

Design aspects of evolutionary algorithms

Variation operators – Crossover

- Crossover typically takes two individuals and results in one or two offspring individuals
 - Also crossover of more than two individuals possible
 - Often generalisations of the two-individual case
- Distinct crossover methods for various search spaces
- Crossover parameter *p_c* specifies the probability with which crossover (and not mutation) is applied for one selected individual
- In some cases (e.g. binary coded numbers) not all positions in the individual string are allowed to apply crossover on

Machine Learning and Pervasive Computing

calculation for every bit independently

Evolutionary

Design aspects of evolutionary algorithms Discussion

Fitness value calculation Most of the computational time is typically consumed by the fitness calculation Prevent re-calculation for individuals Dynamic data structures that support search and insert

Outline

Local random search

Metropolis random search

Simulated annealing

Tabu search

Evolutionary random search Overview History Limitations Design aspects
