Data Link Layer

Chapter 1: The Data Link Layer

o Our goals:

o understand principles behind data link layer services:

- o reliable transmission of data over a link
- o error detection, correction
- o sharing a broadcast channel: multiple access
- o link layer addressing

o instantiation and implementation of various link layer technologies

Link Layer

Link Layer: Introduction

Some terminology:

- hosts and routers are **nodes**
- communication channels that connect adjacent nodes along communication path are **links**
  - wired links
  - wireless links
  - LANs
- layer-2 packet is a **frame,** encapsulates datagram

data-link layer has responsibility of transferring datagram from one node to adjacent node over a link

Link layer: context

- datagram transferred by different link protocols over different links:
  - e.g., Ethernet on first link, frame relay on intermediate links, 802.11 on last link
- each link protocol provides different services
  - e.g., may or may not provide reliable data transfer (rdt) over link

transportation analogy

- trip from Göttingen to Princeton
  - train: Göttingen -> airport
  - plane: FRA -> NYC
  - limo: NYC -> Princeton
- tourist = datagram
- transport segment = communication link
- transportation mode = link layer protocol
- travel agent = routing algorithm

Link Layer Services

o *1. framing, link access:*

- o encapsulate datagram into frame, adding header, trailer
- o channel access if shared medium
- o "MAC" addresses used in frame headers to identify source and destination
  - different from IP address!

o *2. reliable delivery between adjacent nodes*

- o we will cover these so called Automatic repeat request (ARQ) algorithms in detail later
- o seldom used on low bit-error link (fiber, some twisted pair)
- o wireless links: high error rates
  - Q: why both link-level and end-end reliability?
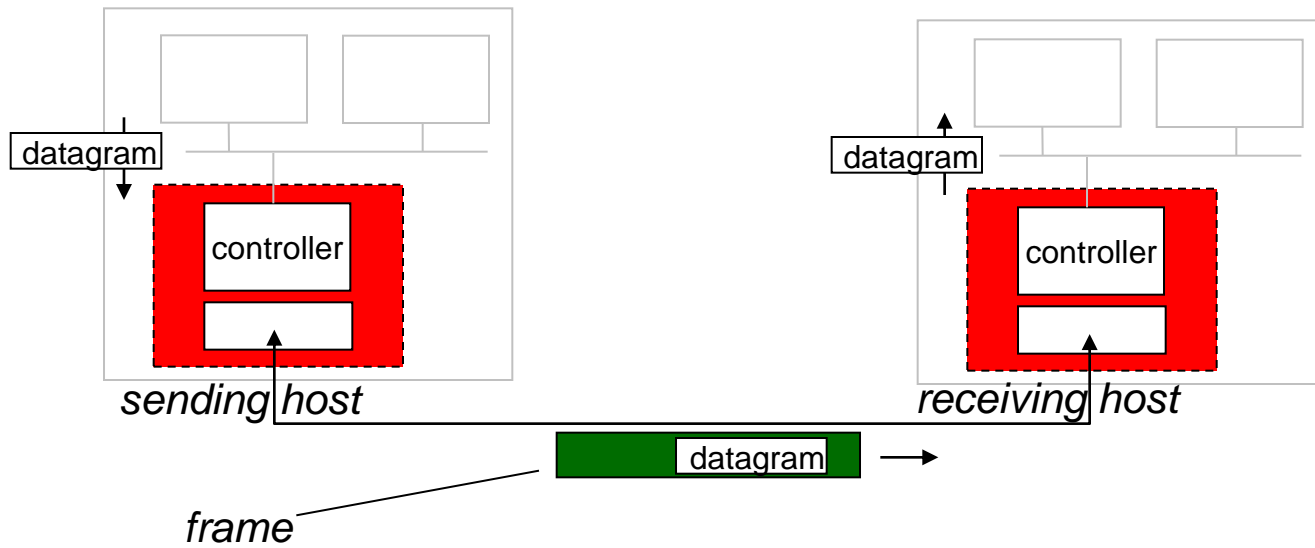

Link Layer Services (more)

- *3. flow control:*
  - pacing between adjacent sending and receiving nodes

- *4. error detection*:
  - errors caused by signal attenuation, noise.
  - receiver detects presence of errors:
    - signals sender for retransmission or drops frame

- 5. error correction:
  - receiver identifies *and corrects* bit error(s) without resorting to retransmission

- *6. half-duplex and full-duplex*
  - with half duplex, nodes at both ends of link can transmit, but not at same time

Where is the link layer implemented?

o in each and every host

o link layer implemented in "adaptor" (aka *network interface card* NIC)

    o Ethernet card, PCMCI card, 802.11 card

    o implements link, physical layer

o attaches into host's system buses

o combination of hardware, software, firmware

host schematic

application

physical
transmission

network adapter card

Adaptors Communicating

o sending side:
   o encapsulates datagram in frame
   o adds error checking bits, rdt, flow control, etc.

o receiving side
   o looks for errors, rdt, flow control, etc
   o extracts datagram, passes to upper layer at receiving side

Link Layer

- 5.1 Introduction and services
- 5.2 Error detection and correction
- 5.3 Multiple access protocols
- 5.4 Link-layer Addressing
- 5.5 Ethernet

- 5.6 Link-layer switches
- 5.7 PPP
- 5.8 Link Virtualization: ATM. MPLS

Error Detection

EDC= Error Detection and Correction bits (redundancy)
D   = Data protected by error checking, may include header fields

• Error detection not 100% reliable!
   • protocol may miss some errors, but rarely
   • larger EDC field yields better detection and correction
Parity Checking

Single Bit Parity:

Detect single bit errors

Two Dimensional Bit Parity:

Detect *and correct* single bit errors

no errors   correctable single bit error

Internet checksum

Goal: detect "errors" (e.g., flipped bits) in transmitted packet (note: used at transport layer *only*)
Sender:

○ treat segment contents as sequence of 16-bit integers

○ checksum: addition (1's complement sum) of segment contents

○ sender puts checksum value into UDP checksum field

Receiver:

○ compute checksum of received segment

○ check if computed checksum equals checksum field value:

  ○ NO - error detected

  ○ YES - no error detected. *But maybe errors nonetheless?*

Checksumming: Cyclic Redundancy Check

o view data bits, D, as a binary number

o choose r+1 bit pattern (generator), G

o goal: choose r CRC bits, R, such that

   o <D,R> exactly divisible by G (modulo 2)

   o receiver knows G, divides <D,R> by G. If non-zero remainder: error detected!

   o can detect all burst errors less than r+1 bits

o widely used in practice (Ethernet, 802.11 Wi-Fi, ATM)

```
←————— d bits —————→ ←— r bits —→
┌──────────────────────┬──────────────┐
│ D: data bits to be sent │ R: CRC bits  │    bit
└──────────────────────┴──────────────┘    pattern
```

$$D * 2^r \quad XOR \quad R$$

mathematical formula

CRC Example

Want:
$$D \cdot 2^r \text{ XOR } R = nG$$

equivalently:

$$D \cdot 2^r = nG \text{ XOR } R$$

equivalently:

if we divide $D \cdot 2^r$ by G, want remainder R

$$R = \text{remainder}\left[\frac{D \cdot 2^r}{G}\right]$$

```
                              101011
        1001 ) 101110000

```

Link Layer

- 5.1 Introduction and services
- 5.2 Error detection and correction
- 5.3 Multiple access protocols
- 5.4 Link-layer Addressing
- 5.5 Ethernet

- 5.6 Link-layer switches
- 5.7 PPP
- 5.8 Link Virtualization: ATM, MPLS

Multiple Access Links and Protocols
Two types of "links":

o point-to-point
- o PPP for dial-up access
- o point-to-point link between Ethernet switch and host

o broadcast (shared wire or medium)
- o old-fashioned Ethernet
- o upstream HFC
- o 802.11 wireless LAN
shared wire (e.g., cabled Ethernet)

shared RF (e.g., 802.11 WiFi)

shared RF (satellite)

humans at a cocktail party (shared air, acoustical)

Multiple Access protocols

o single shared broadcast channel

o two or more simultaneous transmissions by nodes: interference

    o collision if node receives two or more signals at the same time

multiple access protocol

o distributed algorithm that determines how nodes share channel, i.e., determine when node can transmit

o communication about channel sharing must use channel itself!

    o no out-of-band channel for coordination

Ideal Multiple Access Protocol

Broadcast channel of rate R bps

1. when one node wants to transmit, it can send at rate R.

2. when M nodes want to transmit, each can send at average rate R/M

3. fully decentralized:
   o no special node to coordinate transmissions
   o no synchronization of clocks, slots

4. simple

MAC Protocols: a taxonomy

Three broad classes:

o **Channel Partitioning**

- o divide channel into smaller "pieces" (time slots, frequency, code)
- o allocate piece to node for exclusive use

o **Random Access**

- o channel not divided, allow collisions
- o "recover" from collisions

o **"Taking turns"**

- o nodes take turns, but nodes with more to send can take longer turns

Channel Partitioning MAC protocols: TDMA

TDMA: time division multiple access

- access to channel in "rounds"
- each station gets fixed length slot (length = pkt trans time) in each round
- unused slots go idle
- example: 6-station LAN, 1,3,4 have pkt, slots 2,5,6 idle
Channel Partitioning MAC protocols: FDMA

FDMA: frequency division multiple access

- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: 6-station LAN, 1,3,4 have pkt, frequency bands 2,5,6 idle

FDM cable

frequency bands

time
Random Access Protocols

o When node has packet to send

   o transmit at full channel data rate R.

   o no *a priori* coordination among nodes

o two or more transmitting nodes ➜ "collision",

o random access MAC protocol specifies:

   o how to detect collisions

   o how to recover from collisions (e.g., via delayed retransmissions)

o Examples of random access MAC protocols:

   o slotted ALOHA

   o ALOHA

   o CSMA, CSMA/CD, CSMA/CA

Slotted ALOHA

Assumptions:

- all frames same size
- time divided into equal size slots (time to transmit 1 frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

Operation:

- when node obtains fresh frame, transmits in next slot
  - *if no collision:* node can send new frame in next slot
  - *if collision:* node retransmits frame in each subsequent slot with prob. p until success

Slotted ALOHA
Pros:

o single active node can continuously transmit at full rate of channel

o highly decentralized: only slots in nodes need to be in sync

o simple

Cons:

o collisions, wasting slots

o idle slots

o nodes may be able to detect collision in less than time to transmit packet

o clock synchronization

Slotted Aloha efficiency

Efficiency : long-run fraction of successful slots (many nodes, all with many frames to send)

○ *suppose:* N nodes with many frames to send, each transmits in slot with probability *p*

○ prob that given node has success in a slot = $p(1-p)^{N-1}$
○ prob that *any* node has a success = $Np(1-p)^{N-1}$

○ max efficiency: find p* that maximizes $Np(1-p)^{N-1}$

○ for many nodes, take limit of $Np^*(1-p^*)^{N-1}$ as N goes to infinity, gives:

Max efficiency = 1/e = .37

At best: channel used for useful transmissions 37% of time!

!

Pure (unslotted) ALOHA

o unslotted Aloha: simpler, no synchronization

o when frame first arrives

   o transmit immediately

o collision probability increases:

   o frame sent at t_0 collides with other frames sent in $[t_0-1, t_0+1]$

will overlap
with start of
← i's frame →

will overlap
with end of
← i's frame →

node i frame

t_0-1 t_0 t_0+1

Pure Aloha efficiency

P(success by given node) = P(node transmits) ·

P(no other node transmits in $[p_0-1,p_0]$) ·

P(no other node transmits in $[p_0-1,p_0]$

$= p \cdot (1-p)^{N-1} \cdot (1-p)^{N-1}$

$= p \cdot (1-p)^{2(N-1)}$

… choosing optimum p and then letting n -> infty ...

$= 1/(2e) = .18$

even *worse* than slotted Aloha!

CSMA (Carrier Sense Multiple Access)

CSMA: listen before transmit:

If channel sensed idle: transmit entire frame

o   If channel sensed busy, defer transmission

o   human analogy: don't interrupt others!

CSMA collisions

collisions *can* still occur:
propagation delay means
two nodes may not hear
each other's transmission

collision:
entire packet transmission
time wasted

note:
role of distance & propagation
delay in determining collision
probability

spatial layout of nodes

CSMA/CD (Collision Detection)

CSMA/CD: carrier sensing, deferral as in CSMA
- collisions *detected* within short time
- colliding transmissions aborted, reducing channel wastage

- collision detection:
    - easy in wired LANs: measure signal strengths, compare transmitted, received signals
    - difficult in wireless LANs: received signal strength overwhelmed by local transmission strength

- human analogy: the polite conversationalist

CSMA/CD collision detection
"Taking Turns" MAC protocols

channel partitioning MAC protocols:

- ○ share channel *efficiently* and *fairly* at high load
- ○ inefficient at low load: delay in channel access, 1/N bandwidth allocated even if only 1 active node!

Random access MAC protocols

- ○ efficient at low load: single node can fully utilize channel
- ○ high load: collision overhead

"taking turns" protocols

look for best of both worlds!

"Taking Turns" MAC protocols

Polling:

o master node "invites" slave nodes to transmit in turn

o typically used with "dumb" slave devices

o concerns:
  o polling overhead
  o latency
  o single point of failure (master)

master

slaves

"Taking Turns" MAC protocols

Token passing:

o control **token** passed from one node to next sequentially.

o token message

o concerns:
  - token overhead
  - latency
  - single point of failure (token)

(nothing to send)

T

data
Summary of MAC protocols

o *channel partitioning,* by time, frequency or code

    o Time Division, Frequency Division

o *random access* (dynamic),

    o ALOHA, S-ALOHA, CSMA, CSMA/CD

    o carrier sensing: easy in some technologies (wire), hard in others (wireless)

    o CSMA/CD used in Ethernet

    o CSMA/CA used in 802.11

o *taking turns*

    o polling from central site, token passing

    o Bluetooth, FDDI, IBM Token Ring
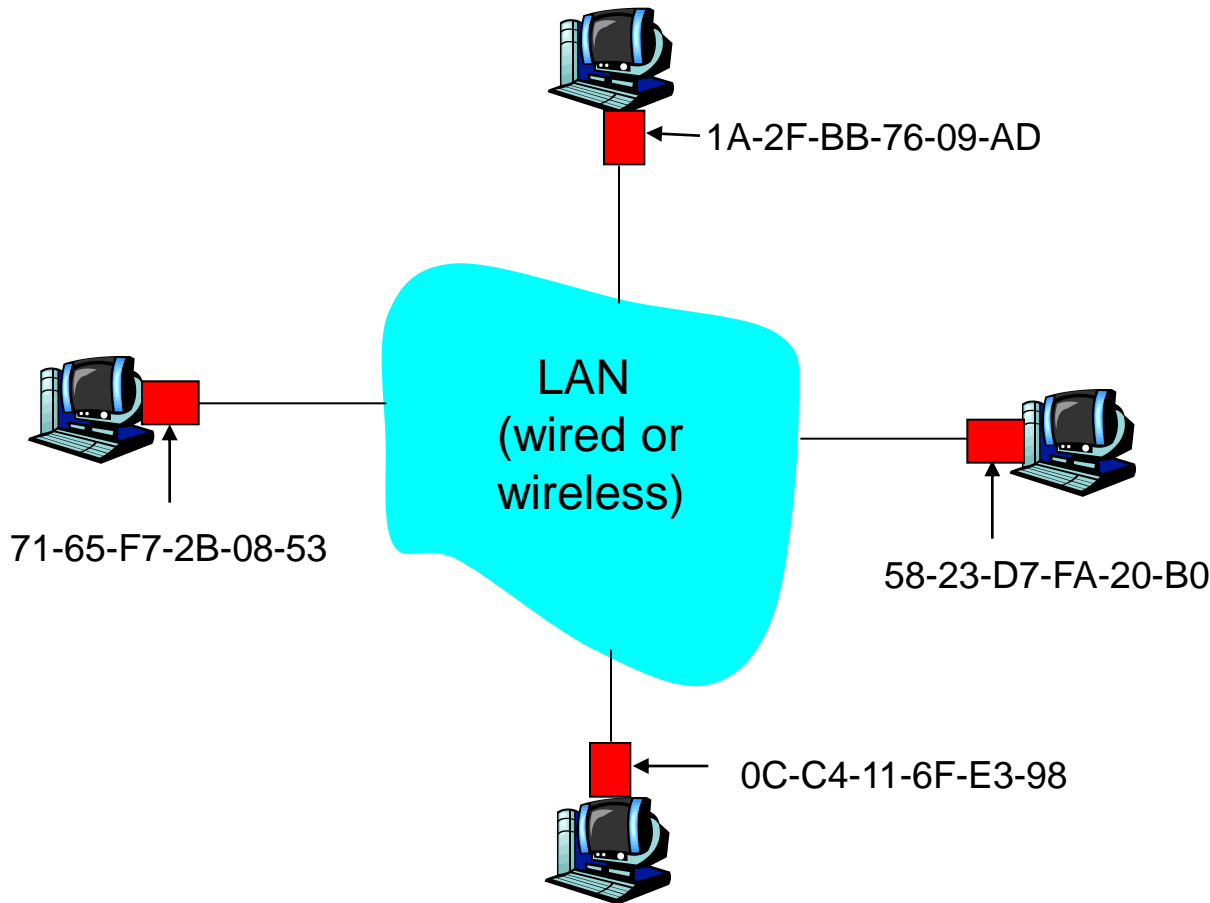

Link Layer

- 5.4 Link-Layer Addressing
- 5.5 Ethernet

- 5.6 Link-layer switches
- 5.7 PPP
- 5.8 Link Virtualization: ATM, MPLS

MAC Addresses and ARP

o 32-bit IP address:

  o *network-layer* address

  o used to get datagram to destination IP subnet

o MAC (or LAN or physical or Ethernet) address:

  o function: *get frame from one interface to another physically-connected interface (same network)*

  o 48 bit MAC address (for most LANs)

    • burned in NIC ROM, also sometimes software settable

LAN Addresses and ARP

Each adapter on LAN has unique LAN address

1A-2F-BB-76-09-AD

Broadcast address =
FF-FF-FF-FF-FF-FF

LAN
(wired or
wireless)

71-65-F7-2B-08-53

58-23-D7-FA-20-B0

= adapter

0C-C4-11-6F-E3-98

LAN Address (more)

o MAC address allocation administered by IEEE

o manufacturer buys portion of MAC address space (to assure uniqueness)

o analogy:

      (a) MAC address: like Social Security Number

      (b) IP address: like postal address

o MAC flat address ➜ portability

    o can move LAN card from one LAN to another

o IP hierarchical address NOT portable

   o address depends on IP subnet to which node is attached

ARP: Address Resolution Protocol

Question: how to determine MAC address of B knowing B's IP address?

o Each IP node (host, router) on LAN has ARP table

o ARP table: IP/MAC address mappings for some LAN nodes

< IP address; MAC address; TTL>

o TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

137.196.7.88

ARP protocol: Same LAN (network)

- A wants to send datagram to B, and B's MAC address not in A's ARP table.
- A broadcasts ARP query packet, containing B's IP address
  - dest MAC address = FF-FF-FF-FF-FF-FF
  - all machines on LAN receive ARP query
- B receives ARP packet, replies to A with its (B's) MAC address
  - frame sent to A's MAC address (unicast)

- A caches (saves) IP-to-MAC address pair in its ARP table until information becomes old (times out)
  - soft state: information that times out (goes away) unless refreshed
- ARP is "plug-and-play":
  - nodes create their ARP tables *without intervention from net administrator*
Addressing: routing to another LAN

walkthrough: send datagram from A to B via R

assume A knows B's IP address

111.111.111.112

R

49-BD-D2-C7-56-2A

CC-49-DE-D0-AB-7D

o two ARP tables in router R, one for each IP network (LAN)

- A creates IP datagram with source A, destination B
- A uses ARP to get R's MAC address for 111.111.111.110
- A creates link-layer frame with R's MAC address as dest, frame contains A-to-B IP datagram

  This is a really important example – make sure you understand!
- A's NIC sends frame
- R's NIC receives frame
- R removes IP datagram from Ethernet frame, sees its destined to B
- R uses ARP to get B's MAC address
- R creates frame containing A-to-B IP datagram sends to B

Link Layer

- 5.1 Introduction and services
- 5.2 Error detection and correction
- 5.3 Multiple access protocols
- 5.4 Link-Layer Addressing
- 5.5 Ethernet

- 5.6 Link-layer switches
- 5.7 PPP
- 5.8 Link Virtualization: ATM and MPLS
Ethernet

"dominant" wired LAN technology:

○ cheap $20 for NIC

○ first widely used LAN technology

○ simpler, cheaper than token LANs and ATM
○ kept up with speed race: 10 Mbps – 10 Gbps
Metcalfe's Ethernet sketch

Star topology

o bus topology popular through mid 90s
  o all nodes in same collision domain (can collide with each other)
o today: star topology prevails
  o active *switch* in center
 o each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

bus: coaxial cable

switch

star

Ethernet Frame Structure

Sending adapter encapsulates IP datagram (or other network layer protocol packet) in Ethernet frame

Preamble:

o 7 bytes with pattern 10101010 followed by one byte with pattern 10101011

o used to synchronize receiver, sender clock rates

Ethernet Frame Structure (more)

o Addresses: 6 bytes
  o if adapter receives frame with matching destination address, or with broadcast address (eg ARP packet), it passes data in frame to network layer protocol
  o otherwise, adapter discards frame

o Type: indicates higher layer protocol (mostly IP but others possible, e.g., Novell IPX, AppleTalk)

o CRC: checked at receiver, if error is detected, frame is dropped

| Preamble | Dest. Address | Source Address | | Data | CRC |

↑ Type
Ethernet: Unreliable, connectionless

o **connectionless:** No handshaking between sending and receiving NICs

o **unreliable:** receiving NIC doesn't send acks or nacks to sending NIC

  o stream of datagrams passed to network layer can have gaps (missing datagrams)

  o gaps will be filled if app is using TCP

  o otherwise, app will see gaps

o Ethernet's MAC protocol: unslotted CSMA/CD

Ethernet CSMA/CD algorithm

1. NIC receives datagram from network layer, creates frame

2. If NIC senses channel idle, starts frame transmission If NIC senses channel busy, waits until channel idle, then transmits

3. If NIC transmits entire frame without detecting another transmission, NIC is done with frame !

4. If NIC detects another transmission while transmitting, aborts and sends jam signal

5. After aborting, NIC enters **exponential backoff**: after mth collision, NIC chooses K at random from $\{0,1,2,\ldots,2^m\text{-}1\}$. NIC waits $K \cdot 512$ bit times, returns to Step 2

Ethernet's CSMA/CD (more)

Jam Signal: make sure all other transmitters are aware of collision; 48 bits

Bit time: .1 microsec for 10 Mbps Ethernet ;
for K=1023, wait time is about 50 msec

Exponential Backoff:

o *Goal*: adapt retransmission attempts to estimated current load

   o heavy load: random wait will be longer

o first collision: choose K from {0,1}; delay is K· 512 bit transmission times

o after second collision: choose K from {0,1,2,3}…

o after ten collisions, choose K from {0,1,2,3,4,…,1023}

CSMA/CD efficiency

○ t_{prop} = max prop delay betw. 2 nodes in LAN

○ t_{trans} = time to transmit max-size frame

$$efficiency = \frac{1}{1 + 5t_{prop}/t_{trans}}$$

o efficiency goes to 1

    ○ as t_{prop} goes to 0

    ○ as t_{trans} goes to infinity

o better performance than ALOHA: and simple, cheap, decentralized!

802.3 Ethernet Standards: Link & Physical Layers

o *many* different Ethernet standards
  - o common MAC protocol and frame format
  - o different speeds: 2 Mbps, 10 Mbps, 100 Mbps, 1Gbps, 10G bps
  - o different physical layer media: fiber, cable

application
transport
network
link
