

Computer Networks

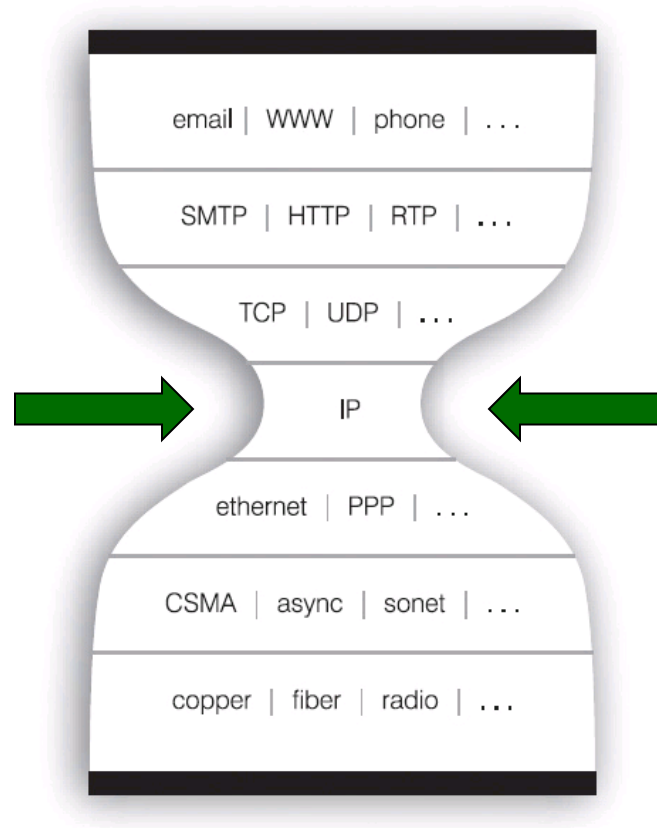

Homework #4

Niklas Neumann
25 November 2010

Internet Protocol Architecture

- Why is the Internet Protocol sometimes described as “narrow waist”? What are the advantages and disadvantages of such an architecture?

Internet Protocol Architecture

© Jonathan L. Zittrain (<http://yupnet.org/zittrain/archives/13>)

Internet Protocol Architecture

- Single common tie between multiple upper and lower layer protocols
- Barrier for evolvement of protocol stack

What kind of switching fabrics are there and how do they work?

- Bus switching
 - Fabric connects ports by means of a bus that is shared among all ports
- Memory switching
 - Fabric connects ports by means of a common memory that is used by all ports
- Crossbar switching
 - Fabric can connect any input port to any output port directly

When and where does buffering occur? What are its effects?

- Input ports:
 - Fabric slower than incoming traffic
- Output ports:
 - Datarate from fabric is faster than outgoing data rate
- Buffering introduces queueing delays and ultimately leads to loss
- Head-of-line blocking: Packet is queued at an **input port**, following packets must wait until that packet is processed

In an IP datagram: what is the header checksum for and where is it calculated?

- Used for error-checking of the header
 - By intermediate routers
 - By the destination
- Calculated
 - At the source
 - At every intermediate router after decrementing the time-to-live value

Fragmentation

- Assume you have a 3,600 byte long datagram which needs to be fragmented for a 1,300 bytes MTU. Please fill the following table with the data of the resulting datagrams.

| Datagram No. | Length | Frag. Flag | Offset |
|--------------|-------------------|------------|--------|
| 1 | 1300 (1280+20) | 1 | 0 |
| 2 | 1300 (1280+20) | 1 | 160 |
| 3 | 1040 (1020+20) | 0 | 320 |
| 4 | | | |

Tip: IP Address Conversion (Decimal to Binary)

- Make yourself a table:

| Power | 2^7 | 2^6 | 2^5 | 2^4 | 2^3 | 2^2 | 2^1 | 2^0 |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Value | 128 | 64 | 32 | 16 | 8 | 4 | 2 | 1 |
| Rest | | | | | | | | |
| Bit | | | | | | | | |

- For each octet:
 - Put octet number into first „rest“ cell
 - $\text{Bit} = (\text{value} \geq \text{rest} ? 1 : 0)$
 - $\text{Rest}_{\text{next}} = \text{Rest}_{\text{prev}} - \text{Bit}_{\text{prev}} \times \text{Value}_{\text{prev}}$
 - Rinse and Repeat

Tip: IP Address Conversion (Example)

- First octet of 66.135.207.138:

| Power | 2^7 | 2^6 | 2^5 | 2^4 | 2^3 | 2^2 | 2^1 | 2^0 |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Value | 128 | 64 | 32 | 16 | 8 | 4 | 2 | 1 |
| Rest | | | | | | | | |
| Bit | | | | | | | | |

- Result:

| Power | 2^7 | 2^6 | 2^5 | 2^4 | 2^3 | 2^2 | 2^1 | 2^0 |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Value | 128 | 64 | 32 | 16 | 8 | 4 | 2 | 1 |
| Rest | 66 | 66 | 2 | 2 | 2 | 2 | 2 | 0 |
| Bit | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 0 |

Convert the following IP addresses into their binary notation

- 66.135.207.138
 - 01000010.10000111.11001111.10001010
- 192.35.225.7
 - 11000000.00100011.11100001.00000111

Tip: IP Address Conversion (Binary to Decimal)

- Make yourself a table:

| Power | 2^7 | 2^6 | 2^5 | 2^4 | 2^3 | 2^2 | 2^1 | 2^0 |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Value | 128 | 64 | 32 | 16 | 8 | 4 | 2 | 1 |
| Bit | | | | | | | | |
| Sum | | | | | | | | |

- For each octet:
 - Fill the „Bit“ row with the bits of the octet
 - Fill the sum row:
$$\text{Sum}_{\text{next}} = \text{Sum}_{\text{prev}} + \text{Bit}_{\text{prev}} \times \text{Value}_{\text{prev}}$$

Tip: IP Address Conversion (Example)

- Octet 10000110:

| Power | 2^7 | 2^6 | 2^5 | 2^4 | 2^3 | 2^2 | 2^1 | 2^0 |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| Value | 128 | 64 | 32 | 16 | 8 | 4 | 2 | 1 |
| Bit | | | | | | | | |
| Sum | | | | | | | | |

- Result:

| Power | 2^7 | 2^6 | 2^5 | 2^4 | 2^3 | 2^2 | 2^1 | 2^0 |
|-------|-------|-------|-------|-------|-------|-------|-------|------------|
| Value | 128 | 64 | 32 | 16 | 8 | 4 | 2 | 1 |
| Bit | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 |
| Sum | 128 | 128 | 128 | 128 | 128 | 132 | 134 | 134 |

Convert the following IP addresses into their decimal notion

- 10000110.01001100.01010001.00011001
 - 134.76.81.25
- 11011000.10011110.01010111.00010111
 - 216.158.87.23

Tip: Subnet calculations

- Subnet calculations are used to break a given network into **smaller** pieces
- A (sub-) network mask shows how many bits of an IP address denote the network
 - Decimal: /17
 - Binary: 11111111.11111111.10000000.00000000
 - Hexadecimal: 255.255.128.0

Tip: Subnet calculations

- Given address: 128.30.10.0
 - 10000000.00011110.00001010.00000000
- Given netmask: 17 (= 255.255.128.0)
 - 11111111.11111111.10000000.00000000
- => Network: 128.30.0.0/17
 - 10000000.00011110.00000000.00000000
- => Broadcast: 128.30.127.255
 - 10000000.00011110.01111111.11111111
- => First host: 128.30.0.1
 - 10000000.00011110.00000000.00000001
- => Last host: 128.30.127.254
 - 10000000.00011110.01111111.11111110
- Number of hosts: $2^{15} - 2 = 32,766$

Tip: Subnet calculations (Example)

- Given network: 128.30.0.0/17
- Wanted: Four sub networks
- First step: Find new subnet mask
 - To address four networks we need at least two bits ($2^2 = 4$).
 - The new subnet mask is $17+2 = 19$
- Second step: Find new network addresses (see next slide)
- Third step: Calculate data for new networks (see previous slide)

Tip: Subnet calculations (Example)

- New netmask: 19 (= 255.255.224.0)
 - 11111111.11111111.11100000.00000000
- => New network 1: 128.30.0.0/19
 - 10000000.00011110.00000000.00000000
- => New network 2: 128.30.32.0/19
 - 10000000.00011110.00100000.00000000
- => New network 3: 128.30.64.0/19
 - 10000000.00011110.01000000.00000000
- => New network 4: 128.30.96.0/19
 - 10000000.00011110.01100000.00000000
- Number of hosts: $2^{13} - 2 = 8,190$

Subnet calculation

- A provider has been assigned the network 128.30.0.0/22 and wants to divide it to accommodate two customers: Customer A has 100 hosts and Customer B has 255 hosts. The remainder should be partitioned in blocks as large as possible. Please fill the following table with the data of the resulting sub networks.

| Subnet No. | Network Address | Netmask | Host Range | No. of Hosts |
|--------------|-----------------|-----------------|--------------------------------|--------------|
| 1 Cust. A | 128.30.0.0/25 | 255.255.255.128 | 128.30.0.1 – 128.30.0.126 | 126 |
| 2 Cust B | 128.30.2.0/23 | 255.255.254.0 | 128.30.2.1 – 128.30.3.254 | 510 |
| 3 (free) | 128.30.0.128/25 | 255.255.255.128 | 128.30.0.128 – 128.30.0.254 | 126 |
| 4 (free) | 128.30.1.0/24 | 255.255.224.0 | 128.30.1.1 – 128.30.1.254 | 254 |

Host calculation

- A host has been assigned the IP address 134.76.81.99 and the network mask 255.255.255.240. Please fill the following table with the parameters that result from this assignment.

| | |
|--|-----------------|
| Network address(in CIDR notation a.b.c.d/e) | 134.76.81.96/28 |
| Broadcast address | 134.76.81.111 |

Network Address Translation

- Q: What are the three essential steps a NAT router must perform to provide network address translation?
- Replace source address of outgoing packets
- Remember the corresponding mapping
- Replace destination address of incoming packets

What are the main differences between IPv4 and IPv6?

- Bigger address space in IPv6 (128 bit vs. 32 bit)
- Fixed-length 40 byte header in IPv6
- No fragmentation allowed in IPv6
- No header checksum in IPv6
- Options outside of header in IPv6
- New version of ICMP in IPv6 (ICMPv6)

IP address space

- Q: How large is the IPv6 address space in comparison to the IPv4 address space?
- Increase from 32 to 128 bits
- 340,282,366,920,938,463,463,374,607,431,768,211,456 addresses in total
- 79,228,162,514,264,337,593,543,950,336 times the IPv4 addresses
- Disclaimer: Not a „fair“ comparison as IPv6 addresses are assigned far more coarse grained.

Thank you

Any questions?
